ABSTRACT

Background: Appendicitis is the inflammation of the appendix. It is a disease of the young, with 40% of cases occurring between the ages of 10 and 29 yrs. The present study involves diagnostic study of clinical, laboratory and radiological findings in acute appendicitis. **Materials and methods:** It was a prospective analytical study carried out at department of surgery, Nishtar hospital Multan. To study diagnostic accuracy and value of clinical, laboratory and radiological findings in acute appendicitis, conducted during the period from October 2016 to October 2017. **Results:** It was observed that majority of patients belonged to age group 21-30 years (34%) followed by 31-40 years (26%). The proportion of male cases was 58% while that of female cases was 42%. All patients presented with pain in abdomen and tenderness in right iliac fossa (100%), followed by vomiting (82%). **Conclusions:** Acute appendicitis is more a clinical diagnosis rather than radiological. It is better to use radiological investigations only to confirm the diagnosis of acute appendicitis rather than diagnose it primarily because it is clear from the present study that a significant number of positive cases had been missed radiologically.

KEYWORDS: Acute abdomen, Acute appendicitis, Appendix, Clinical diagnosis.**INTRODUCTION**

Appendicitis is the inflammation of the appendix. It is a disease of the young, with 40% of cases occurring between the ages of 10 and 29 yrs. In 1886, Fitz reported the associated mortality rate of appendicitis to be at least 67% without surgical therapy.^[1] Sir Heneage Ogilvie says "Acute appendicitis is one of the common condition which the surgeon is called upon to treat as an emergency". It requires utmost skill and care of the attending doctor, besides good clinical judgment. Acute appendicitis is the most common surgical cause of acute abdomen. There is no doubt that early diagnosis with prompt surgical intervention is the goal.

In a general hospital most common abdominal operation is appendectomy. This constitutes about 25% of emergency abdominal surgeries in many hospitals, Meloney and his associates estimated that 1 in 100 of population may be expected to get appendicitis every year. There is no known method of prevention of acute appendicitis. The diagnosis of acute appendicitis is predominantly a clinical one, many patients present with a typical history and examination findings. The cause of acute appendicitis is unknown but is probably multifactorial- luminal obstruction, dietary and familial factors have all been suggested. Appendectomy is the

treatment of choice.^[2] Despite technologic advances, the diagnosis of appendicitis is still based primarily on patient's history and the physical examination. Prompt diagnosis and surgical referral may reduce the risk of perforation and prevent complications. The mortality rate in non-perforated appendicitis is <1% but may be as high as 5% or more in young and elderly patients. The present study involves diagnostic study of clinical, laboratory and radiological findings in acute appendicitis.

MATERIALS AND METHODS

It was a prospective analytical study carried out at department of surgery, Nishtar hospital Multan. Study regarding diagnostic accuracy and value of clinical, laboratory and radiological findings in acute appendicitis, conducted during the period from October 2016 to October 2017. In the present study 150 patients admitted to wards with history of pain abdomen (especially with pain in right iliac fossa suggestive of acute appendicitis) within 24-48 hours in the department of General Surgery were included.

We excluded patients with history of pain abdomen of >48 hours duration with clinical symptoms and signs suggestive of appendicular mass or appendicular abscess or diagnosed to be having other pathological conditions like PID, ruptured ectopic, right ureteric calculus,

perforated duodenal ulcer, acute cholecystitis, torsion of omentum, enterocolitis, nonspecific mesenteric lymphadenitis, regional ileitis, obstructed carcinoma of the caecum, Mackle's diverticulum etc.

After admission to the hospital a detailed proforma was filled including clinical history and physical findings, preoperative investigations. On the basis of clinical history and the physical signs a diagnosis of acute appendicitis was made and differentiated from other acute abdomen conditions. After taking the history, patient was examined for general physical examination, and systemic examination and few specific examinations particular for the appendicitis are done. Preliminary hematological investigations and ultrasonography of abdomen and pelvis was done. All the patients were assessed according to modified Alvarado scoring system as below:

Patients with a score of 1 - 4 were not considered likely to have acute appendicitis. Those patients with score of 5 - 6 were considered likely to have acute appendicitis. But not convincing enough to warrant immediate surgery. Those with a score more than 7 were considered to have definitive acute appendicitis.^[3] Score Prediction: 1-4 : Unlikely, 5-6 : Possible, More than: 7 Definitive. Appendix was removed during appendectomies and was inspected for macroscopic abnormalities and microscopic findings evaluated by histopathological findings.

The data was recorded using standard case record proforma and entered using Microsoft Excel software. The statistical analyses performed using the Statistical Package for Social Science (SPSS) version 21 for Windows. Data were expressed as mean values \pm standard deviations (SD) for continuous variables. Frequency and proportions were reported for categorical

variables. The p-value of < 0.05 was considered statistically significant.

RESULTS

The present study was conducted among 150 cases admitted under department of surgery with history of pain in right iliac fossa suggestive of acute appendicitis within 24-48 hours. We recorded and analyzed various demographic variables of the study cases. It was observed that majority of patients belonged to age group 21-30 years (34%) followed by 31-40 years (26%). The proportion of male cases was 58% while that of female cases was 42% (Figure 1) (Figure 2). We analyzed modes of presentation of cases and observed that all patients presented with pain in abdomen and tenderness in right iliac fossa (100%), followed by vomiting (82%).

The cases of acute abdomen were further subjected to various hematological investigations, It was observed that majority of patients presented with leukocytosis (82%) followed by increased neutrophil count 74%, 62% cases had increased C-reactive proteins (Table 1). Study cases were further subjected to ultrasonographic examinations. Among various USG features, it was observed that majority of patients were having congested edematous appendix (80%) and in 3 cases perforated appendix was observed. The findings were also confirmed using histological examinations, it was observed that majority of patients were having inflamed appendix finding (92%), followed by appendicular perforation (4%) (Table 3). After comparative analysis of clinical, radiological and histological findings. The histological findings showed that findings from 144 (96%) patients, were in favor of conditions related to appendicitis as compared to just clinical (92%) or radiological (82%). In the present study the clinical accuracy was more as (sensitivity=92%) compared to radiological accuracy (sensitivity=82%) (Table 4).

Table 1: Distribution of cases according to their various clinical parameters.

Clinical parameters	Number of cases	Percentage	
Clinical presentation	Pain in abdomen	150	100
	Vomiting	123	82
	Fever	120	80
	Tenderness in right iliac fossa	150	100
	Rebound tenderness	43	28.67
Investigation findings	Leukocytosis	123	82
	Increase Neutrophils	111	74
	Increase C-reactive Proteins	93	62
Modified Alvarado Score	<4	00	00
	5-6	03	02
	7-8	18	12
	>8	129	86
Operative as well as histopathological findings	Inflamed Appendix	144	96
	Appendicular perforation	06	04

Table 2: Distribution of cases according to their Ultrasonography findings.

USG Features	Number of Patients	Percentage
Congested Edematous	120	80
Not visualized	27	18
Perforated	03	02
Thickened fibrotic	00	00
Gangrenous	00	00
Total	150	100

Table 3: Comparison of Clinical, Radiological and Histological Findings.

Diagnosis	Positive (%)	Negative (%)	Total (%)
Clinical	138 (92)	12 (08)	150 (100)
Radiological	123 (82)	27 (18)	150 (100)
Histological	144 (96)	06 (04)	150 (100)

Table 4: Diagnostic accuracy of Clinical, Radiological and Histological Findings.

Diagnosis	Sensitivity	Specificity	Positive Predictive Value	Negative Predictive Value
Clinical	92%	50%	97.97%	25%
Radiological	82%	63%	91%	52%
Histological	96%	94%	98.73%	16%

DISCUSSION

The diagnosis of appendicitis is made purely based on history, clinical examination and some laboratory investigations. New diagnostic techniques such as estimation of C-reactive protein, peritoneal aspiration

cytology, scoring and computer analysis, graded compression ultra sonography, computed tomography, non-contrast helical computed tomography and laparoscopy have been introduced in recent years.^[6] The drawback with these techniques is involvement of additional costs and lack of free availability. Due to these factors these modalities have not gained wide acceptance as routine diagnostic investigations of acute appendicitis. Imaging techniques have been shown to add very little. A certain diagnosis can only be obtained at surgery and after pathological examination of surgical specimen.^[4,5]

In the present study, we emphasized on the importance of clinical examination and utilization of modified Alvarado score in making a confident diagnosis of acute appendicitis and thereby decreasing the negative appendectomy rate. The present cross-sectional study was conducted to study diagnostic accuracy and value of clinical, laboratory and radiological findings in acute appendicitis among total 150 patients admitted under department of surgery with history of pain in abdomen within 24-48 hours especially with pain in right iliac fossa suggestive of acute appendicitis during the study period of October 2016 to October 2017.

The present study has shown that modified Alvarado scoring system (MASS) provides high degree of sensitivity, specificity, PPV and accuracy in the diagnosis of acute appendicitis by showing lower negative appendectomy rate and high positive predictive value. It is therefore recommended that modified Alvarado score should be used to improve the diagnostic accuracy of acute appendicitis and subsequently reduce negative appendectomy and complication rates. A modified Alvarado score above 7 should indicate appendectomy without the need for further imaging

studies. This study proves that modified Alvarado scoring system is very useful scoring system for diagnosis of acute appendicitis. It may help making early diagnosis and prevent further complications, reduce numbers of negative appendectomies, it is better than other scoring systems because it includes wide spectrum of symptoms and signs and laboratory investigations and finally it helps in reducing necessity of ultrasonography and CT scan which has become now-a-days gold standard for diagnosis of acute appendicitis. Ultrasound is unnecessary when one's degree of clinical suspicion is high. However, the additional information provided by ultrasound does improve diagnostic accuracy in the case of a negative clinical diagnosis. It is better to use radiological investigations only to confirm the diagnosis of acute appendicitis rather to diagnose it primarily because it is clear from the present study that a significant number of positive cases had been missed radiologically.

In the present study, it was observed that majority of patients were in age group 21-30 years (34%) followed by 31-40 years (26%) The majority of patients were males (58%) and females were 42%. The findings were compared with studies done by Nshuti R,^[7] Kapoor S et al,^[8] and A. Gligorievski et al^[9] were mean age was 26±12, 28 ±11 and 31 ±10 years respectively. A. Gligorievski et al,^[9] (2010) demonstrated the value of the ultrasound (US) as an excellent diagnostic modality in evaluation of the appendix in 124 cases with history and physical examination of acute appendicitis observed with aged 15-57, with peak incidence in second decade of life with mean age of 31 ±10 years. Kapoor S et al^[8] (2016) evaluated the efficiency of clinical examination, radiological investigations, intraoperative and histopathological examination in diagnosis of acute appendicitis among fifty consecutive patients suspected of acute appendicitis observed mean age of 28 ±11 years. In this study it was observed that all patients presented with pain in abdomen and tenderness in right iliac fossa (100%), followed by vomiting (82%). Majority of patients presented with leukocytosis (82%) followed by increased neutrophil count 74%. The modified Alvarado Score showed that majority of patients were having score >8 (86%). Nshuti R^[7] in their study found pain as a major symptom among 90% whereas Kapoor S et al^[8] (2016) observed pain as a most common symptom among 92%. In this study it was observed that majority of patients were having congested edematous appendix (80%). It was observed that majority of patients were having congested finding (96%), followed by perforated appendix (4%). The majority of patients were having inflamed appendix finding (92%), followed by appendicular perforation (4%). The histological findings showed 144 (96%) patients positive finding related to appendicitis as compared to radiological (82%).

The clinical accuracy was observed to be more as (sensitivity=92%) compared to radiological accuracy (sensitivity=82%) in the present study. In this study it was observed that positive predictive value is 97.97% and negative predictive value is 25%. The findings

related to clinical presentation were compared with studies done by Richard Nshuti, they found sensitivity of clinical findings as 93%, Specificity (86%), PPV (93.3%) and NPV (66.7%).

CONCLUSIONS

Acute appendicitis is more a clinical diagnosis rather than radiological. It is better to use radiological investigations only to confirm the diagnosis of acute appendicitis rather to diagnose it primarily because it is clear from the present study that a significant number of positive cases had been missed radiologically. Ultrasound is unnecessary when one's degree of clinical suspicion is high. However, the additional information provided by ultrasound does improve diagnostic accuracy in the case of a negative clinical diagnosis.
